THE REMOTE SUPPORT PROGRAM · JOB SHEET

Upload the holding page to theremotesupportprogram.com

Replace the page currently on the website with the new one. It is a single file and the whole job takes about ten minutes. No server access, no DNS, nothing to install.

Version 2 · 16 September 2026 Owner: Clint, Anywhere IT queries@theremotesupportprogram.com

What you are doing, and what you are not

The website `theremotesupportprogram.com` is hosted on **xneelo shared hosting**, managed through a control panel called **konsoleH**. There is one page on it today. You are replacing that page with a newer one.

That is nearly the whole job. There is **one** setting to change at the end, in step 6, and it is named there. Apart from that you are **not** touching DNS, email, or any other setting. If a screen you are on is about anything else, you are in the wrong place — back out.

What Clint gives you

ITEM	NOTES
`index.html`	One file, about 23 KB. This is the whole website — there are no images, stylesheets or other files that go with it.
konsoleH login	Username and password for the control panel. Ask Clint; do not go looking for them.

DO NOT RENAME THE FILE

It must be uploaded as `index.html`, exactly, in lower case. A web server looks for that precise name. `Index.html`, `index.htm` or `index (1).html` will not be served, and the site will look unchanged or show a list of files instead.

Check the name **before** you upload — browsers often add `(1)` to a downloaded file when one of the same name already exists.

1 Sign in to konsoleH `KONSOLEH.XNEELO.CO.ZA`

Open `https://konsoleh.xneelo.co.za` and sign in with the details Clint gave you.

Once in, select the domain `theremotesupportprogram.com`. Some accounts list several domains and open on a summary page; others go straight into the one domain. Either is normal — you just need to be looking at this domain before the next step.

> **IF YOU CANNOT SIGN IN**
>
> Stop and go back to Clint. There are two separate xneelo systems — konsoleH for hosting and email, and a different one for cloud servers. Only konsoleH is used here, and logins for one do not work on the other.

2 Open the file manager `IN KONSOLEH`

Look for **File Manager** under the web hosting section of the menu. konsoleH has been redesigned more than once, so it may sit under a heading such as *Web*, *Hosting* or *Tools*. It is the option that lets you browse folders and upload files.

Now open the folder called `public_html`. Everything the public website serves lives in that folder, and nothing outside it is part of the website.

> **IF YOU CANNOT FIND THE FILE MANAGER**
>
> Use FTP instead — it does the same job. The server is `www40.cpt3.host-h.net`, and FTP usernames and passwords are created and shown in konsoleH under **FTP Users**. Connect with FileZilla or any FTP client, then open `public_html` and carry on from step 3.

3 Move the old page out of the way `IN PUBLIC_HTML`

Look in `public_html` for a file called `index.html`, and also one called `index.htm`. One or both will be there.

Rename each one you find by adding `.old` to the end, so `index.html` becomes `index.html.old`. Most file managers offer Rename when you right-click a file, or from a menu next to it.

Renaming rather than deleting means the old page can be put straight back if anything is wrong, which is worth ten seconds.

> **THIS STEP IS THE ONE PEOPLE SKIP**
>
> If the old `index.html` is still there when you upload the new one, one of two things happens: the upload is refused, or it overwrites without warning. If it is refused, the website carries on showing the old page and it looks as though the upload did nothing.

> **LEAVE EVERYTHING ELSE ALONE**
>
> Do not delete any other file or folder in `public_html`, even if it looks unused. If the folder contains things you were not expecting, that is fine — carry on.

4 Upload the new page `INTO PUBLIC_HTML`

Use the **Upload** button in the file manager and choose the `index.html` Clint gave you. Make sure you are still inside `public_html` when you do it — not in the folder above it.

When it finishes, you should see `index.html` listed, roughly 23 KB in size, with today's date.

> **CHECK THE NAME ONE MORE TIME**
>
> If it uploaded as `index (1).html` or anything other than `index.html`, rename it now. This is the single most common reason the site does not change.

5 Check it worked `IN A BROWSER`

Open the website:

```
https://theremotesupportprogram.com
```

You should see a **dark navy page** headed *"Remote support that carries your brand"*, with purple buttons, and further down a pricing section showing **R500** and four region buttons — South Africa, US & Canada, United Kingdom, Europe.

> **HOW TO TELL THE NEW PAGE FROM THE OLD ONE**
>
> The **old** page is also dark navy, which makes them very easy to confuse. Two reliable differences:
>
> - The new page has a **pricing section** with R500 and four region buttons. The old one has no pricing at all.
> - The new page's email address is `queries@theremotesupportprogram.com`. The old one says `info@`.
>
> If you see no pricing, or an `info@` address, you are still looking at the old page. Go back to step 3 and check the rename and the file name.

> **IF THE BROWSER SHOWS AN OLD VERSION**
>
> Press **Ctrl** + **F5** to force a reload, or open the site in a private window. Browsers hold on to a page they have seen before, which can make a correct upload look as though it did nothing.
>
> You can also check the site directly on the hosting server, which bypasses caching entirely: `http://theremotesupportprogram.com.www40.cpt3.host-h.net`

6 Switch on Force HTTPS IN KONSOLEH

The site has a valid security certificate, so `https://` works. Visitors who type the address without it still arrive on the unencrypted `http://` version, and this setting sends them to the secure one automatically.

In konsoleH, find the **Web Server Config** settings for the domain and turn on **Force HTTPS** (it may be called *Redirect to HTTPS* or *SSL redirect*). Save.

Then check it. Type the address with `http://` deliberately:

```
http://theremotesupportprogram.com
```

The browser should jump to `https://` on its own, with a padlock showing.

> **DO THIS LAST, AND ONLY IF STEP 5 WORKED**
>
> If `https://theremotesupportprogram.com` did not load cleanly with a padlock in step 5, **stop and tell Clint.** Forcing HTTPS when the certificate is not working takes the website off the internet completely, and it is not obvious from inside konsoleH that it has happened.
>
> If the site stops loading after you change this, switch the setting back off. That undoes it immediately.

Hand back to Clint

Tell him these four things

- [ ] The new page is live on the interim address, and you can see the pricing section with R500 and the four region buttons.
- [ ] What the old file was renamed to, and that it is still in `public_html`.
- [ ] That `https://theremotesupportprogram.com` loads with a padlock, and that typing `http://` now jumps to it.
- [ ] Anything in `public_html` that looked unexpected. Do not act on it — just say what you saw.

If something goes wrong

WHAT YOU SEE	WHAT IT MEANS
The page has not changed	Almost always the file name. Check it is `index.html` exactly, in lower case, and that the old `index.html` and `index.htm` were renamed.
A list of file names instead of a website	There is no file called `index.html` in `public_html`. The upload landed in the wrong folder, or under the wrong name.
The page loads but looks plain and unstyled	Only part of the file uploaded. Upload it again and let it finish.
A security warning on the domain	Not expected any more - the certificate is in place. Stop, do not change any HTTPS setting, and tell Clint.
Anything to do with email	Stop. Email is set up and working on this hosting, and it is not part of this job.

PUTTING IT BACK

If the new page is wrong in any way, rename `index.html` to `index.html.new` and rename `index.html.old` back to `index.html`. The site returns to exactly what it was, immediately.
